1 Abstract

As many of you know, systemd is the new Fedora init system, starting with F14, and it is also on its way to being adopted in a number of other distributions as well (for example, OpenSUSE). For administrators systemd provides a variety of new features and changes and enhances the administrative process substantially. This blog story is the first part of a series of articles I plan to post roughly every week for the next months. In every post I will try to explain one new feature of systemd. Many of these features are small and simple, so these stories should be interesting to a broader audience. However, from time to time we'll dive a little bit deeper into the great new features systemd provides you with.

2 Verifying Bootup

Traditionally, when booting up a Linux system, you see a lot of little messages passing by on your screen. As we work on speeding up and parallelizing the boot process these messages are becoming visible for a shorter and shorter time only and be less and less readable – if they are shown at all, given we use graphical boot splash technology like Plymouth these days. Nonetheless the information of the boot screens was and still is very relevant, because it shows you for each service that is being started as part of bootup, wether it managed to start up successfully or failed (with those green or red [OK] or [FAILED] indicators). To improve the situation for machines that boot up fast and parallelized and to make this information more nicely available during runtime, we added a feature to systemd that tracks and remembers for each service whether it started up successfully, whether it exited with a non-zero exit code, whether it timed out, or whether it terminated abnormally (by segfaulting or similar), both during start-up and runtime. By simply typing systemctl in your shell you can query the state of all services, both systemd native and SysV/LSB services:

```
[root@lambda] ~# systemctl
[root@lambda] "# systemctl
UNIT
dev-hugepages.automount
dev-mqueue.automount
proc-sys-fs-binfmt_misc.automount
sys-kernel-debug.automount
sys-kernel-security.automount
sys-devices-pc...0000:02:00.0 - net-eth0.device
sys-devices-virtual-tty-tty9.device
-mount
boot.mount
                                                                                            ACTIVE
                                                                                LOAD
                                                                                                                   SUB
                                                                                loaded
                                                                                                                   running
                                                                                            active
active
                                                                                loaded
                                                                                                                   running
                                                                                loaded
                                                                                                                   waiting
                                                                                loaded
                                                                                                                   waiting
                                                                                                                   plugged

                                                                                                                   exited
lvm2-monitor.service
mdmonitor.service
modem-manager.service
                                                                                loaded
                                                                                            active
                                                                                                                   exited
                                                                                loaded
                                                                                                                   running
netfs.service
NetworkManager.service
                                                                                loaded
                                                                                loaded
                                                                                            active
                                                                                                                   running
ntpd.service
                                                                                loaded
listed. Pass -- all to see inactive units, too.
```

(I have shortened the output above a little, and removed a few lines not relevant for this blog post.) Look at the ACTIVE column, which shows you the high-level state of a service (or in fact of any kind of unit systemd maintains, which can be more than just services, but we'll have a look on this in a later blog posting), whether it is **active** (i.e. running), **inactive** (i.e. not running) or in any other state. If you look closely you'll see one item in the list that is marked

maintenance and highlighted in red. This informs you about a service that failed to run or otherwise encountered a problem. In this case this is ntpd. Now, let's find out what actually happened to ntpd, with the *systemctl status* command:

```
[root@lambda] "# systemctl status ntpd.service
ntpd.service — Network Time Service
Loaded: loaded (/etc/systemd/system/ntpd.service)
Active: maintenance
Main: 953 (code=exited, status=255)
CGroup: name=systemd:/systemd-1/ntpd.service
[root@lambda] "#
```

This shows us that NTP terminated during runtime (when it ran as PID 953), and tells us exactly the error condition: the process exited with an exit status of 255.

In a later system version, we plan to hook this up to ABRT, as soon as this enhancement request is fixed. Then, if systemctl status shows you information about a service that crashed it will direct you right-away to the appropriate crash dump in ABRT.

Summary: use *systemctl* and *systemctl status* as modern, more complete replacements for the traditional boot-up status messages of SysV services. *systemctl status* not only captures in more detail the error condition but also shows runtime errors in addition to start-up errors. That's it for this week, make sure to come back next week, for the next posting about systemd for administrators!

3 Which Service Owns Which Processes?

On most Linux systems the number of processes that are running by default is substantial. Knowing which process does what and where it belongs to becomes increasingly difficult. Some services even maintain a couple of worker processes which clutter the "ps" output with many additional processes that are often not easy to recognize. This is further complicated if daemons spawn arbitrary 3rd-party processes, as Apache does with CGI processes, or cron does with user jobs.

A slight remedy for this is often the process inheritance tree, as shown by "ps xaf". However this is usually not reliable, as processes whose parents die get reparented to PID 1, and hence all information about inheritance gets lost. If a process "double forks" it hence loses its relationships to the processes that started it. (This actually is supposed to be a feature and is relied on for the traditional Unix daemonizing logic.) Furthermore processes can freely change their names with PR_SETNAME or by patching argv[0], thus making it harder to recognize them. In fact they can play hide-and-seek with the administrator pretty nicely this way.

In systemd we place every process that is spawned in a control group named after its service. Control groups (or cgroups) at their most basic are simply groups of processes that can be arranged in a hierarchy and labelled individually. When processes spawn other processes these children are automatically made members of the parents cgroup. Leaving a cgroup is not possible for unprivileged processes. Thus, cgroups can be used as an effective way to label processes after the service they belong to and be sure that the service cannot escape from the label, regardless how often it forks or renames itself. Furthermore this can be used to safely kill a service and all processes it created, again with no chance of escaping.

In today's installment I want to introduce you to two commands you may use to relate systemd services and processes. The first one, is the well known ps command which has been updated to show cgroup information along the other process details. And this is how it looks:

```
pid , user , cgroup , args
CGROUP
                                                                                                                                                                                                                                                     COMMAND
                  \begin{array}{cc} 2 & \text{root} \\ 3 & \text{root} \end{array}
                                                                                                                                                                                                                                                      [kthreadd]
\= [ksoftirqd/0]
                                                                                                                                                                                                                                                     \_ [flush -8:0]
/sbin/init
                                                                      name=systemd:/systemd-1

                                                                       name=systemd
                                                                                                                                        /user/lennart
                                                                       name=systemd:/user/lennart/1
                                                                                                                                                                                                                                                                              \_ empathy
```

(Note that this output is shortened, I have removed most of the kernel threads here, since they are not relevant in the context of this blog story)

In the third column you see the cgroup systemd assigned to each process. You'll find that the udev processes are in the name=systemd:/systemd-1/sysinit.service cgroup, which is where systemd places all processes started by the sysinit.service service, which covers early boot.

My personal recommendation is to set the shell alias psc to the ps command line shown above:

```
alias psc='ps xawf -eo pid, user, cgroup, args'
```

With this service information of processes is just four keypresses away! A different way to present the same information is the systemd-cgls tool we ship with systemd. It shows the cgroup hierarchy in a pretty tree. Its output looks like this:
